

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

### Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

- + *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

### About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at <http://books.google.com/>

## PREFACE.

---

THE preparation of the American Ephemeris and Nautical Almanac was begun in the latter part of the year 1849, in accordance with an act of Congress, approved on the 3d of March of that year. An account of this preparation and the values of the constants adopted will be found in the Preface and Appendix of the first volume, for the year 1855.

In the volume for 1865 the Star Ephemeris was greatly enlarged; new places of the Stars adopted; the form for Moon Culminations and Moon-Culminating Stars changed so that less space was required; Mean Solar Time, instead of Sidereal Time, used in the dates of the Ephemeris for the Meridian of Washington; BESSEL's notation in the formulæ for star-reductions substituted for BAILY's; and several other changes of less importance were made.

In the present volume the Ephemerides of Venus and Mars are made to conform more rigidly to the adopted elements; the Stars arranged in the order of their right ascensions; the Ephemeris of 51 Cephei, instead of  $\epsilon$  Ursæ Minoris, given for each day; the explanations of the arrangement and use of the Tables revised, so as to adapt them to the wants of operators at sea or in the field, who are out of reach of other sources of information; and several statements in the Appendix corrected.

Tables for correcting  $A$  and  $B$  for small terms of nutation; Reductions of Star-Places in the volumes for 1865-9 to those adopted in the volume for 1870; an Ephemeris of Neptune for 1866-9 derived from Professor NEWCOMB's Tables; and a list of Occultations in 1868 and 1869, visible in the Territory of the United States west of the Mississippi river, have been added to the Appendix.

J. H. C. COFFIN,  
*Prof. Math. U. S. Navy, Superintendent.*

## CHRONOLOGICAL ERAS AND CYCLES.

### CHRONOLOGICAL ERAS.

THE YEAR 1869, WHICH COMPRISES THE LATTER PART OF THE 93D AND THE BEGINNING OF THE 94TH YEAR OF THE INDEPENDENCE OF THE UNITED STATES OF AMERICA, CORRESPONDS TO—

The year 6582 of the Julian Period;

“ 7377–78 of the Byzantine era;

“ 5629–30 of the Jewish era;

“ 2622 since the foundation of Rome, according to Varro;

“ 2616 since the beginning of the era of Nabonassar, which has been assigned to Wednesday, the 26th of February, of the 3967th year of the Julian Period, corresponding according to the chronologists to the 747th, and according to the astronomers to the 746th year before the birth of Christ.

“ 2645 of the Olympiads, or the first year of the 662d Olympiad, commencing in July, 1869, if we fix the era of the Olympiads at 775½ years before Christ, or near the beginning of July of the year 3938 of the Julian Period;

“ 2181 of the Grecian era, or the era of the Seleucidæ;

“ 1585 of the era of Diocletian.

The year 1286 of the Mohammedan era, or the era of the Hegira, begins on the 13th of April, 1869.

The first day of January of the year 1869 is the 2,403,699th day since the commencement of the Julian Period.

### CHRONOLOGICAL CYCLES.

Dominical Letter . . . . .	C	Solar Cycle . . . . .	2
Epact . . . . .	17	Roman Indiction . . . . .	12
Lunar Cycle or Golden Number . . . . .	8	Julian Period . . . . .	6582

## SYMBOLS AND ABBREVIATIONS.

---

### SIGNS OF THE PLANETS, &c.

☉	The Sun.	♂	Mars.
☾	The Moon.	♃	Jupiter.
☿	Mercury.	♄	Saturn.
♀	Venus.	♅	Uranus.
♁ or ♂	The Earth.	♆	Neptune.

### SIGNS OF THE ZODIAC.

Spring signs.	1.	♈	Aries.	Autumn signs.	7.	♎	Libra.
	2.	♉	Taurus.		8.	♏	Scorpio.
	3.	♊	Gemini.		9.	♐	Sagittarius.
Summer signs.	4.	♋	Cancer.	Winter signs.	10.	♑	Capricornus.
	5.	♌	Leo.		11.	♒	Aquarius.
	6.	♍	Virgo.		12.	♓	Pisces.

### ASPECTS.

♌	Conjunction, or having the same Longitude or Right Ascension.			
☐	Quadrature, or differing 90° in	"	"	"
♌	Opposition, or differing 180° in	"	"	"

### ABBREVIATIONS.

♊	Ascending Node.	'	Minutes of Arc.
♋	Descending Node.	"	Seconds of Arc.
N.	North.	h	Hours.
E.	East.	m	Minutes of Time.
°	Degrees.	s	Seconds of Time.

BESSEL'S FORMULÆ OF REDUCTION FOR THE FIXED STARS,

WITH DR. PETERS'S COEFFICIENTS, AND BESSEL'S NOTATION.

$$\begin{aligned} A &= \tau - 0.34242 \sin \Omega + 0.00410 \sin 2 \Omega - 0.02519 \sin 2 \odot + 0.00294 \sin (\odot + 82^\circ 20'). \\ B &= -9''.2237 \cos \Omega + 0''.0896 \cos 2 \Omega - 0''.5507 \cos 2 \odot - 0''.0093 \cos (\odot + 280^\circ 41'). \\ C &= -20''.4451 \cos \omega \cos \odot. \\ D &= -20''.4451 \sin \odot. \\ E &= -0''.0470 \sin \Omega + 0''.0015 \sin 2 \Omega - 0''.0034 \sin 2 \odot. \end{aligned}$$

$$a = 46''.0819 + 20''.0548 \sin a \tan \delta.$$

$$b = \cos a \tan \delta.$$

$$c = \cos a \sec \delta.$$

$$d = \sin a \sec \delta.$$

$$a' = 20''.0548 \cos a.$$

$$b' = -\sin a.$$

$$c' = \tan \omega \cos \delta - \sin a \sin \delta.$$

$$d' = \cos a \sin \delta.$$

$\mu$  = the annual proper motion in right ascension.

$\mu'$  = the annual proper motion in declination.

$\tau$  = the time reckoned from Jan. 0<sup>d</sup> — .407, when the sun's mean longitude was  $280^\circ$ , and expressed in fractional parts of a tropical year.

$\odot$  = the sun's true longitude.

$\Omega$  = the longitude of the moon's ascending node.

$\omega$  = the obliquity of the ecliptic.

$a$  = the star's mean right ascension for the beginning of the year.

$\delta$  = the star's mean declination for the beginning of the year.

$a'$  = the star's apparent right ascension at the time  $\tau$ .

$\delta'$  = the star's apparent declination at the time  $\tau$ .

$$a' - a = A a + B b + C c + D d + E + \tau \mu.$$

$$\delta' - \delta = A a' + B b' + C c' + D d' + \tau \mu'.$$

The following formulæ may also be used by putting

$$f = 46''.0819 A + E.$$

$$i = C \tan \omega.$$

$$g \cos G = 20''.0548 A.$$

$$h \sin H = C.$$

$$g \sin G = B$$

$$h \cos H = D.$$

$$a' - a = f + \tau \mu + g \sin (G + a) \tan \delta + h \sin (H + a) \sec \delta.$$

$$\delta' - \delta = \tau \mu' + g \cos (G + a) + h \cos (H + a) \sin \delta + i \cos \delta.$$

Table V. and VI. of the Appendix contain the following terms, which may be added to A and B, when great accuracy is required:

$$\begin{aligned} \Delta A &= -0.00405 \sin 2 \varrho + 0.00135 \sin (\varrho - \Gamma') + 0.00025 \sin (2 \odot - \Omega) \\ &\quad + 0.00010 \sin 2 (\odot - \Gamma') - 0.00005 \sin 2 (\odot - \Omega) + 0.00009 \sin (2 \Gamma' - \Omega) \\ &\quad + 0.00005 \cos \Gamma' + 0.00004 \sin 2 \Gamma' - 0.00011 \sin (3 \odot - \Gamma'). \end{aligned}$$

$$\begin{aligned} \Delta B &= -0''.0886 \cos 2 \varrho + 0''.0067 \cos (2 \odot - \Omega) + 0''.0024 \cos (2 \Gamma' - \Omega) \\ &\quad - 0''.0023 \sin \Gamma' + 0''.0008 \cos 2 \Gamma' - 0''.0027 \cos (3 \odot - \Gamma'). \end{aligned}$$

In which—

$\varrho$  = the moon's mean longitude.

$\Gamma$  = the longitude of the sun's perigee.

$\Gamma'$  = the longitude of the moon's perigee.

Other terms, which became sensible for stars very near the pole, will be found on page 504.

## MOON'S EQUATOR.

The moon's libration in latitude and longitude, at any time, may be found by means of the following formulas and tables:

$I$  = the inclination of the ecliptic of the moon's equator =  $1^{\circ} 28'.8$ .

$\Omega$  = mean longitude of the moon's ascending node (see page 250).

= mean longitude of the descending node of the moon's equator.

$C$  = the angle at the centre of the moon's disc made by a meridian of the moon with the circle of declination, reckoned from north to east on the apparent disc.

$i$ ,  $\Delta$ ,  $\Omega'$ , and  $\zeta$  are defined on the next page, where their values for the year are given.

$\lambda$ ,  $\beta$ ,  $\alpha'$ , and  $\delta'$  the apparent longitude, latitude, right ascension, and declination of the moon affected with parallax.

$\lambda'$  = the selenocentric longitude of the earth, reckoned on the moon's equator from its descending node.

$$\left. \begin{aligned} \Delta \lambda &= -0'.57 \sin 2(\Omega - \lambda) \\ a &= \sin I \cos(\Omega - \lambda) \\ \tan B &= \tan I \sin(\Omega - \lambda) \\ \lambda' &= \lambda + \Delta \lambda + a b \end{aligned} \right\} \text{ See table, VII of the Appendix.}$$

The libration in latitude,  $b = B - \beta$ ,

" " longitude,  $l = \lambda' - \zeta$ .

$$\sin C = \sin i \frac{\cos(\lambda' + \Delta - \Omega)}{\cos \delta'} = -\sin i \frac{\cos(\alpha' - \Omega')}{\cos b}.$$

## LOGARITHMS OF MASSES.

Sun's = 1.

Mercury, 93.3129	The Earth, 94.44985	Jupiter, 96.979689	Uranus, 95.60371
Venus, 94.4089	Mars, 93.57176	Saturn, 96.45573	Neptune, 95.72630

## ECLIPSES IN 1869.

In the year 1869 there will be four Eclipses; two of the Sun, and two of the Moon.

I. A Partial Eclipse of the Moon, January 27, 1869, visible at Washington, with the following elements:—

Washington mean time of  $\delta$  in Right Ascension, January 27 <sup>d</sup> 8 <sup>h</sup> 43 <sup>m</sup> 30.7.

Sun's Right Ascension	20 <sup>h</sup> 42 <sup>m</sup> 41.08	Hourly Motion	10.32
Moon's Right Ascension	8 42 41.08	" "	155.91
Sun's Declination	—18° 12' 53.9"	Hourly Motion	+ 0' 39.5"
Moon's Declination	+17 25 2.4	" "	— 6 25.4
Sun's Equa. Hor. Par.	8.7	True Semidiameter	16 14.4
Moon's Equa. Hor. Par.	61 1.0	" "	16 36.8

From these elements may deduced the following results:—

Moon enters Penumbra, January	27 <sup>d</sup> 6 <sup>h</sup> 9.8 <sup>m</sup>	Washington mean time.
Moon enters Shadow	27 7 20.5	" "
Middle of the Eclipse	27 8 30.2	" "
Moon leaves Shadow	27 9 39.8	" "
Moon leaves Penumbra	27 10 50.5	" "

First contact of Shadow with Moon's limb 50° from north point towards the East, when the Moon is in the zenith, in longitude 287° 41' West from Washington, and in latitude 17° 40' North.

Last contact of Shadow with Moon's limb 31° from north point towards the West, when the Moon is in the zenith, in longitude 321° 4' West from Washington, and in latitude 17° 25' North.

Magnitude of Eclipse = 0.458 (Moon's diameter = 1).

II. An Annular Eclipse of the Sun, February 10, 1869, invisible at Washington, with the following elements:—

Washington mean time of  $\delta$  in Right Ascension, February 10 <sup>d</sup> 20 <sup>h</sup> 20 <sup>m</sup> 37.6.

Sun's and Moon's R. A.	21 <sup>h</sup> 41 <sup>m</sup> 4.80	Hourly Motions	9.84 and 119.21
Sun's Declination	—13° 53' 2.6"	Hourly Motion	+ 0' 49.6"
Moon's Declination	—14 27 39.1	" "	+ 7 6.2
Sun's Equa. Hor. Par.	8.7	True Semidiameter	16 11.9
Moon's Equa. Hor. Par.	54 3.5	" "	14 43.1

OUTLINES AND PATH OF THE PENUMBRA, AND THE CENTRAL  
LINE OF THE ANNULAR ECLIPSE OF FEBRUARY 10, 1869.

From these elements may be deduced the following results:—

Eclipse begins on the Earth, February 10<sup>d</sup> 17<sup>h</sup> 46<sup>m</sup>.7, Washington mean time, in longitude 3° 12'.3 West from Washington, and in latitude 35° 39'.0 South.

Central Eclipse begins on the Earth 19<sup>h</sup> 5<sup>m</sup>.7, in longitude 29° 55'.3 West from Washington, and in latitude 50° 8'.8 South.

Central Eclipse at Noon 20<sup>h</sup> 20<sup>m</sup>.6, in longitude 301° 32'.0 West from Washington, and in latitude 54° 6'.4 South.

Central Eclipse ends on the Earth 22<sup>h</sup> 11<sup>m</sup>.0, in longitude 232° 39'.7 West from Washington, and in latitude 24° 41'.3 South.

Eclipse ends on the Earth 23<sup>h</sup> 30<sup>m</sup>.0, in longitude 256° 27'.3 West from Washington, and in latitude 9° 47'.4 South.

A and  $\mu$  are given in the Table for Penumbra, and the values of log E, log F, log G, and log H may be obtained from corresponding values for Penumbra, by numerically increasing log E and decreasing log F by 0.000002, and by numerically decreasing log G by 0.000039 and increasing log H by 0.000041.

III. A Partial Eclipse of the Moon, July 22, 1869, invisible at Washington, with the following elements:—

Washington mean time of  $\delta$  in Right Ascension, July 22 <sup>d</sup> 21 <sup>h</sup> 3 <sup>m</sup> 59.9.

Sun's Right Ascension	<sup>h</sup> <sup>m</sup> <sup>s</sup> 8 11 34.85	Hourly Motion	<sup>s</sup> 9.92
Moon's Right Ascension	20 11 34.85	" "	131.53
Sun's Declination	+20° 1' 1.2	Hourly Motion	— 0' 31.0
Moon's Declination	—19 22 5.3	" "	+ 3 56.6
Sun's Equa. Hor. Par.	8.4	True Semidiameter	15 45.0
Moon's Equa. Hor. Par.	55 28.3	" "	15 6.2

\* In units of the sixth place of decimals.

From these elements may be deduced the following results:—

Moon enters Penumbra, July	22 <sup>d</sup> 18 <sup>h</sup> 11.9 <sup>m</sup>	Washington mean time.
Moon enters Shadow	22 19 30.9	" "
Middle of the Eclipse	22 20 54.4	" "
Moon leaves Shadow	22 22 17.9	" "
Moon leaves Penumbra	22 23 36.9	" "

First contact of Shadow with Moon's limb 127° from north point towards the East, when the Moon is in the zenith, in longitude 111° 59' West from Washington, and in latitude 19° 35' South.

Last contact of Shadow with Moon's limb 141° from north point towards the West, when the Moon is in the zenith, in longitude 152° 18' West from Washington, and in latitude 19° 24' South.

Magnitude of Eclipse = 0.566 (Moon's diameter = 1).

IV. A Total Eclipse of the Sun, August 7, 1869, visible at Washington, with the following elements:—

Washington mean time of $\zeta$ in Right Ascension, August				7 <sup>d</sup> 4 <sup>h</sup> 37 <sup>m</sup> 44.6 <sup>s</sup> .
Sun's and Moon's R. A.	9 <sup>h</sup> 11 <sup>m</sup> 13.33 <sup>s</sup>	Hourly Motions	9.55 and	151.20
Sun's Declination	+16° 14' 48.1"	Hourly Motion	— 0	42.4
Moon's Declination	+16 57 33.3	" "	— 7	37.7
Sun's Equa. Hor. Par.	8.5	True Semidiameter	15	46.8
Moon's Equa. Hor. Par.	60 22.0	" "	16	26.2

From these elements may be deduced the following results:—

Eclipse begins on the Earth, August 7<sup>d</sup> 2<sup>h</sup> 29<sup>m</sup>.7, Washington mean time, in longitude 138° 37'.4 West from Washington, and in latitude 36° 53'.3 North.

Central Eclipse begins 3<sup>h</sup> 37<sup>m</sup>.8, in longitude 165° 26'.4 West from Washington, and in latitude 52° 41'.9 North.

Central Eclipse at Noon 4<sup>h</sup> 37<sup>m</sup>.7, in longitude 68° 4'.6 West from Washington, and in latitude 61° 46'.9 North.

Central Eclipse ends 6<sup>h</sup> 7<sup>m</sup>.6, in longitude 350° 26'.4 West from Washington, and in latitude 31° 15'.2 North.

Eclipse ends on the Earth 7<sup>h</sup> 15<sup>m</sup>.6, in longitude 13° 10'.0 West from Washington, and in latitude 14° 48'.9 North.

\* Whole occultation below the horizon of Washington.

† Immersion below the horizon of Washington.

‡ Emersion below the horizon of Washington.

The *Angles of Position*, for the points of contact, are for *direct vision*, and are reckoned from the moon's *North Point* and from its *Vertex* towards the West. For *inverted image*, add 180° to the angles given.

# 458 JUPITER'S SATELLITES, 1869.

Phases of the Eclipses of the Satellites for an Inverting Telescope.

I.

III.

II.

IV.

Not Eclipsed.

The Satellites are not visible from March 16th to May 18th, Jupiter being too near the Sun.

20	2 16.6	27	9 56.5	14	3 3.1	31	16 8.6

In the following Tables  $x$  and  $y$  are the rectangular coördinates for each Satellite, referred to the centre of the primary and the major and minor axis of the apparent ellipse described by the Satellite.  $x$  is positive on the *east* side of the planet; negative on the *west* side.  $y$  is positive when *north*; negative when *south*.

$x'$  and  $y'$  are the coördinates which correspond to a constant value of the major axis and maximum value of the minor axis, as seen from the sun at its mean distance.

The factors by which  $x'$  and  $y'$  must be multiplied to obtain the coördinates  $x$  and  $y$  at any time, are given for each Satellite on pages 489-490.

$p$  is the inclination of the minor axis of the apparent ellipse to the circle of declination; reckoned from the North, + towards the East.

# JUPITER'S SATELLITES, 1869. 485

COORDINATES IN THE MEAN APPARENT ELLIPSE, DESCRIBED BY THE  
SATELLITE, AND FOR THE MEAN DISTANCE OF JUPITER  
FROM THE SUN, FOR THE TIME ( $t$ ) AFTER GEO-  
CENTRIC SUPERIOR CONJUNCTION.

## ON THE ARRANGEMENT AND USE OF THE TABLES IN THIS EPHEMERIS.

---

THIS Ephemeris is divided into two distinct parts. One part is designed for the special use of NAVIGATORS, and is adapted to the Meridian of Greenwich.

The other part is suited to the convenience of ASTRONOMERS, on this continent particularly, and is adapted to the Meridian of Washington.

### THE NAUTICAL PART.

This part contains the Ephemeris of the Sun and Moon; the distances of the Moon from the centres of the Sun and the four most conspicuous Planets, and from certain Fixed Stars; the Ephemeris of the Planets Venus, Mars, Jupiter, and Saturn; and the Mean Places of 198 principal Fixed Stars for the beginning of the year 1869.

*Time.*—Astronomers make use of several different kinds of time; an explanation of the nature of which, and of the method of passing from one to another, properly precedes an explanation of the uses of the Ephemeris.

*Sidereal Time.*—Sidereal Time is measured by the daily motion of the stars, or, as it is used by astronomers, by the daily motion of that point in the equator from which the true right ascensions of the stars are counted. This point is the vernal equinox, and its hour angle is called the *Sidereal Time*. Astronomical clocks are regulated to sidereal time.

A *Sidereal Day* is the interval of time between the transit of the vernal equinox over any meridian, and its next succeeding return to the same meridian. It is divided into 24 hours. The sidereal hours are counted from 0 to 24, commencing with the instant of the passage of the true vernal equinox over the upper meridian, and ending with its return to the same meridian.

The vernal equinox is not a fixed, but a movable, point on the equator. Its motion is composed of two parts: precession, which is proportional to the time, and is combined with the daily motion of the heavens; and nutation, which is periodical. In consequence of the latter, the daily motion of the equinox is not strictly a uniform measure of time, and the Sidereal Time in common use might therefore be called *Apparent Sidereal Time*; and *Mean Sidereal Time* would be that reckoned from the transit of the mean equinox; but the irregularity referred to cannot exceed 2<sup>s</sup>.3 in a period of nineteen years, and is, therefore, of no practical importance.

*Solar Time.*—Solar Time is measured by the daily motion of the sun. A *Solar Day* is the interval of time between two successive transits of the sun over the same meridian; and the hour angle of the sun is called *Solar Time*. This is the most natural and direct measure of time. But the intervals between the successive returns of the sun to the meridian are not exactly equal, but depend upon the variable motion of the sun in right ascension.

The want of uniformity in the sun's motion in right ascension arises from two different causes; one, that the sun does not move in the equator, but in the ecliptic; the other, that the sun's motion in the ecliptic is not uniform.

To avoid the irregularity in time caused by the want of uniformity in the sun's motion, a fictitious sun, called a *Mean Sun*, is supposed to move in the equator with a uniform velocity

*Mean Time*, which is perfectly equable in its increase, is measured by the motion of this *Mean Sun*; the latter at certain periods agrees with the real sun, then again is in advance of it, and at other times is behind it. The clocks in ordinary use, and chronometers used by Navigators, are regulated to *mean* time.

*True or Apparent Time* is measured by the motion of the real sun.

The difference between the *true* and *mean* time is called the *Equation of Time*. By means of it we pass from *true* to *mean* time, or the reverse. Thus, if the *true* time be given, the *mean* time corresponding to it will be obtained by adding or subtracting the equation of time, according to the precept at the head of the column in which it is found, on page I. of the Calendar. If the *mean* time be given, the *true* time is obtained by applying the equation of time as directed by the precept on page II. of the Calendar.

*Day*.—The *civil day*, according to the customs of society, commences at midnight, and comprises twenty-four hours from one midnight to the next following. The hours are counted from 0 to 12 from midnight to noon, after which they are again reckoned from 0 to 12 from noon to midnight. Thus the day is divided into two periods of 12 hours each; the first of which is marked A. M., the last is marked P. M.

The *astronomical day* commences at noon of the civil day of the same date. It also comprises twenty-four hours, but they are reckoned from 0 to 24, and from the noon of one day to that of the next following. The astronomical, as well as the civil time, may be either *apparent*, or *mean*, according as it is reckoned from *apparent* noon, or from *mean* noon.

The civil day begins twelve hours before the astronomical day; therefore the first part of the *civil day* answers to the last part of the preceding *astronomical day*, and the last part of the *civil day* to the first part of the same *astronomical day*. Thus, January 10th, 2<sup>h</sup>. A. M., *civil time*, is January 9th, 14<sup>h</sup>., *astronomical time*; and January 9th, 2<sup>h</sup>. P. M., *civil time*, is also January 9th, 2<sup>h</sup>., *astronomical time*. The rule, then, for the transformation of the civil time into astronomical time is this: If the civil time is marked A. M., take one from the date, and add twelve to the hours, and the result is the astronomical time wanted; if the civil time is marked P. M., take away the designation P. M., and the astronomical time is had without further change.

If the longitude be expressed in time, and, when it is *west*, added to the local time, or, when it is *east*, subtracted from the local time, the result is the corresponding Greenwich time. If the local astronomical time is used, the result is the *Greenwich astronomical time*, which ordinarily is required for the use of this Part.

THE CALENDAR.—The Calendar is divided into twelve months, and to each month are assigned eighteen pages, of which the contents are as follows:

Page I. contains the *Apparent Right Ascension and Declination* of the Sun, and the *Equation of Time* for each Greenwich *apparent* noon. Adjoining columns contain the differences of these quantities for one hour, by means of which they may be calculated for any given Greenwich *apparent* time, by multiplying this difference by the hours and parts of an hour from Greenwich *apparent* noon, and adding the amount to, or subtracting it from, the quantity at noon, according as that quantity is increasing or decreasing. The hourly differences are given for the instant of noon at Greenwich, and, when great accuracy is required, may be first interpolated for *half* the hours and parts of an hour of the Greenwich time.

This page is chiefly used when the sun is observed on the meridian, and the local *apparent* time is 0. Then the longitude from Greenwich expressed in time, if *west*, is the Greenwich *apparent* time, or time *after* Greenwich *apparent* noon;—if *east*, it is time *before* Greenwich *apparent* noon;—and may be employed in reducing the quantities on this page to *apparent* noon at any place.

The Right Ascension of the sun thus reduced is the *Sidereal Time of Local Apparent Noon*. The difference between it and the clock time of the meridian passage of the sun is the error of the clock on sidereal time.

The declination of the sun reduced to the meridian, or apparent noon, of the place, is needed in finding the latitude from a meridian altitude of the sun.

As an example of the use of this page, let the sun's declination be required at noon of January 18th, 1869, in longitude  $146^{\circ} 4' W.$ , or  $+ 9^h 44^m 16^s$ . We first find—

For January 18th, at Greenwich <i>apparent</i> noon,	$20^{\circ} 26' 13.5'' S.$
The diff. for 1 hour, $30''.96$ , multiplied by 9, is	$278.64$
The proportional part for $30^m = \frac{1}{4}^h$ ,	$15.48$
“ “ “ $12^m = \frac{1}{2}^h$ ,	$6.19$
“ “ “ $2^m = \frac{1}{30}^h$ ,	$1.03$
“ “ “ $15^s = \frac{1}{4}$ of $2^m$ ,	$.13$
The sum to be subtracted,	$301.47$ or $5 \ 15 \ N.$
The sun's declination required,	$20 \ 23 \ 12.0 \ S.$

The longitude  $9^h 44^m 16^s = 9^h 44^m.27 = 9^h.738$ ;

and  $30''.96 \times 9.738 = 301''.49 = 5' 1''.49$ ;

which is also the reduction obtained in another way.

If the longitude is  $146^{\circ} 4' E.$ , the reduction,  $5' 1''.5$ , should be added, and the resulting declination becomes  $20^{\circ} 33' 15''.0 S.$

If greater precision is required, the hourly difference may be first interpolated for  $4^h 52^m$  *after* noon for the *west* longitude, or for  $4^h 52^m$  *before* noon for the *east* longitude. This will give, in the first case, the hourly difference  $31''.16$ , and the resulting declination  $20^{\circ} 23' 10''.1 S.$ ; and, in the second case, the hourly difference  $30''.76$ , and the declination  $20^{\circ} 33' 13''.0 S.$

At sea, however, it is ordinarily sufficient to have the declination to the nearest half minute; and the reduction may be found by Table V of Bowditch's *American Practical Navigator*.

The *Equation of Time*, as has been before explained, is the number of minutes and seconds to be added to or subtracted from the *apparent* time, or the time given by an observation of the sun, to obtain the *mean* time. The heading of the column directs the manner in which the equation is to be applied. Where there is a change in the course of the month from addition to subtraction, or the reverse, as in the months of April and June, the two different directions are separated by a line, while a corresponding line below points out the date at which the change takes place. As given on page I. the equation of time is also the *mean* time of *apparent* noon.

On page I. are also given the *Sun's Semidiameter*, which is used in reducing the altitude of a limb of the sun, or the angular distance of the limb from the moon or some other object, to the altitude, or distance, of the centre of the sun; and the *Sidereal Time of the Semidiameter passing the Meridian*, which is employed in obtaining the passage of the sun's centre over the wires of a transit-instrument, when the passage of one limb only has been observed. The quantity found in this column is to be added to the time of transit of the *first* or western limb, to be subtracted from the time of transit of the *second* or eastern limb.

Page II. contains for each Greenwich *mean* noon the *Apparent Right Ascension* and *Declination of the Sun*, the *Equation of Time*, and the *Sidereal Time of Mean Noon*. The hourly changes of these quantities are also given for noon, and may be used in reducing them to any given Greenwich *mean* time. The hourly changes may be first interpolated for half the Greenwich time, when great precision is required.

The Right Ascension and Declination on pages I. and II. are affected by *Aberration*, and therefore denote the *apparent* position of the *true* sun. Page II. is more conveniently used when the *mean* time is known. This is the case in most observations of the sun out of the meridian, when the times have been noted by a clock or chronometer regulated to *mean* time. The quantities can be reduced to mean noon of any place by interpolating for the longitude, as in the example of the sun's declination on page 498.

The sun's declination is required for finding the latitude of the place, the local time, and the sun's azimuth and amplitude, from observations of the sun.

The equation of time is needed in finding the local time, and the latitude from other than meridian observations. The heading of the column directs the manner in which it is to be applied to *mean* time to obtain the *apparent* time.

As given on page II, the equation when *additive* is the apparent time of mean noon; and in general it is the hour angle of the *true* sun at the instant of *mean* noon.

The *Sidereal Time of Mean Noon* is also the *Right Ascension of the Mean Sun*. It may be reduced for the longitude, or to any Greenwich *mean* time, by using the hourly difference,  $9^{\circ}.8565$ ; or by Table III. in the appendix of the *American Ephemeris* for *reducing intervals of mean solar to sidereal time*. Table LI. of Bowditch's *Navigator*, may be used for the same purpose when the nearest quarter of a second only is required.

The sun's right ascension and the sidereal time of mean noon, or right ascension of the mean sun, are useful in converting solar time to sidereal time. If we add the right ascension of the *true* sun to the *apparent* time, or the right ascension of the *mean* sun to the *mean* time, the result will be the *sidereal* time.

The sidereal time of mean noon is also used in converting sidereal time to mean time, by first reducing it for the longitude of the place. Subtracting the reduced value from the given sidereal time, gives the interval of sidereal time from noon. Subtracting from this the corresponding reduction of a *sidereal interval to a mean time interval* in Table II. of the *American Ephemeris*, or Table LII. of Bowditch's *Navigator*, will give the mean time required. This reduction may also be found by multiplying  $9^{\circ}.8296$  by the hours and parts of an hour of the given *sidereal* time.

As examples of the use of page II. :—

1. Let the sun's right ascension and the equation of time be required for 1869, Jan. 24,  $8^{\text{h}} 15^{\text{m}} 16^{\text{s}}$  A. M. mean time at a place whose longitude is  $84^{\circ} 16' \text{ E}$ .

The local astronomical <i>mean</i> time is	Jan. 23, $20^{\text{h}} 15^{\text{m}} 16^{\text{s}}$
The longitude in time,	— $5^{\text{h}} 37^{\text{m}} 4^{\text{s}}$
The Greenwich <i>mean</i> time,	Jan. 23, $14^{\text{h}} 38^{\text{m}} 12^{\text{s}}$ or Jan. 23, 14.6367
<i>Sun's R. A.</i>	
Jan. 23, <i>Noon</i> ,	$20^{\text{h}} 23^{\text{m}} 38.61^{\text{s}}$
H. D. $10^{\circ}.476 \times 14.6367$	$+ 2^{\text{h}} 33.33^{\text{m}}$
	$20^{\text{h}} 26^{\text{m}} 11.94^{\text{s}}$
<i>Equation of time.</i>	
Jan. 23, <i>Noon</i> ,	$12^{\text{m}} 12.46^{\text{s}}$ <i>Subtractive.</i>
H. D. $+ 0^{\circ}.620 \times 14.637$	$+ 9.07^{\text{s}}$
	$12^{\text{m}} 21.53^{\text{s}}$

If greater precision is required, the hourly differences interpolated to  $7^{\text{h}}.3$ , or  $10^{\circ}.466$  for the right ascension, and  $0^{\circ}.610$  for the equation of time, should be used.

The equation of time is *subtractive* from mean time. Its reduction could have been found by Table VI. A. of Bowditch's *Navigator* to seconds only.

2. If the sidereal time is required for the same date and time, we have—

Jan. 23, <i>Noon</i> , the R. A. of the mean sun is	$20^{\text{h}} 11^{\text{m}} 26.15^{\text{s}}$
Add the H. D. $9^{\circ}.8565 \times 14.6367$ , or	$+ 2^{\text{h}} 24.27^{\text{m}}$
Add the local <i>astronomical</i> mean time	$20^{\text{h}} 15^{\text{m}} 16.00^{\text{s}}$
The required sidereal time is (rejecting $24^{\text{h}}$ from the sum)	$16^{\text{h}} 29^{\text{m}} 6.42^{\text{s}}$

The reduction  $2^{\text{h}} 24^{\text{m}}.27$  could have been found in Table III. corresponding to the Greenwich mean time,  $14^{\text{h}} 38^{\text{m}} 12^{\text{s}}$ .

3. 1869, Jan. 24, A. M., at a place whose longitude is  $84^{\circ} 16' E.$ , suppose the sidereal time to be  $16^h 29^m 6^s.42$ , and that the corresponding mean time is required.

The astronomical day is Jan. 23; the longitude in time —  $5^h 37^m 4^s$ , or —  $5^h.618$ .

Jan. 23, the sidereal time of Greenwich noon is	$20^h 11^m 26^s.15$
The H. D. $9^s.8565 \times (-5.618)$ , or the red. for $5^h 37^m 4^s$ in Table III.	— 55.37
The sidereal time of local noon,	$20^h 10^m 30^s.78$
The given sidereal time + $24^h$ ,	$40^h 29^m 6^s.42$
Subtracting the first from the second gives	$20^h 18^m 35^s.64$
— $9^s.8296 \times 20.310$ , or the red. for $20^h 18^m 36^s$ in Table II.,	— 3 19.64

The required mean time,

Jan. 23,  $20^h 15^m 16^s.00$

Page III. contains the *Longitude* and *Latitude of the Sun*, and the *Logarithm of its Distance from the Earth*, at Greenwich Mean Noon of each day. The Longitude is given in two columns, headed  $\lambda$  and  $\lambda'$ ; and one,  $\lambda$ , is the Sun's longitude counted from the true equinox of the date; the other,  $\lambda'$ , is the same coördinate counted from the mean equinox of the beginning of the year. A column of hourly differences enables the computer to obtain the Sun's longitude for any hour from noon. The hourly differences of the logarithm of the Radius Vector are likewise given. The longitudes of the Sun are the true longitudes, not affected by aberration. The latitude is referred to the ecliptic of the date.

The last column on page III. contains the *Mean Time of Sidereal*  $0^h$ , or  $24^h$ —the right ascension of the mean sun. It may be reduced to any meridian by interpolating for the longitude, or to any Greenwich *sidereal* time, by means of the hourly difference, — $9^s.8296$ . The reduction, however, can be taken directly from Table II. of the American Ephemeris, for *reducing intervals of sidereal time to mean solar time*.

This column is used in converting sidereal time to mean time. Let us take as an illustration Example 3, above.

Jan. 23, the mean time of Greenwich sidereal $0^h$ is	$3^h 47^m 56^s.41$
The H. D. — $9^s.8296 \times (-5.618)$ , or the red. for long., Table II.,	+ 55.22
The mean time of local sid. $0^h$ ,	$3^h 48^m 51^s.63$
Add the given sidereal time,	$16^h 29^m 6^s.42$
	$20^h 17^m 58^s.05$
— $9^s.8296 \times 16.485$ , or the red. of sid. time, Table II.,	— 2 42.04

The required mean time,

Jan. 23,  $20^h 15^m 16^s.01$

If the result had been more than  $24^h$ , the mean time of sidereal  $0^h$  should have been taken out for Jan. 22, that is the *preceding* astronomical day. It was, however, readily seen in advance in this example that the result would be much less than  $24^h$ .

Page IV. contains the *Moon's Semidiameter* and *Equatorial Horizontal Parallax* for every mean noon and midnight at Greenwich. Columns adjoining those of the Horizontal Parallax give the change of this quantity in one hour, by means of which it can be reduced to any other Greenwich mean time in the same way as the sun's declination and the equation of time in the preceding examples. The sign *plus* or *minus* (+ or —) prefixed to the hourly differences, shows whether the horizontal parallax is increasing or decreasing.

The reduction of the moon's semidiameter may be readily found from the reduction of the horizontal parallax, by multiplying it by 0.272. It also may be obtained from Table XI. of Bowditch's *Navigator*, or by simply computing the proportional part.

If, for example, the semidiameter of the moon is to be taken out for 1869, Feb. 22,  $9^h P. M.$ , we see that the difference of the semidiameters at noon and midnight of Feb. 22 is  $7''.8$ ; then we say—

as  $12^h : 9^h = 7''.8 : 5''.9$

which is the correction to be added to the semidiameter at noon, because the semidiameter is increasing. The moon's semidiameter, then, for Feb. 22 9<sup>h</sup> is  $16' 8''.1 + 5''.9$ , or  $16' 14''.0$ .

The moon's semidiameter and horizontal parallax are required for all observations of the moon. When great precision is needed, the hourly differences should be first interpolated for half the interval of Greenwich time from noon or midnight, and a correction applied to the horizontal parallax for the latitude of the place of observation.

The *Mean Time of the Moon's Meridian Passage* at Greenwich, which is given on page IV. to minutes and tenths of minutes, is also accompanied with a column of differences for one hour of longitude, by means of which, having the longitude turned into time, the time of the moon's meridian passage at any other place may be computed. The reduction may be taken from BOWDITCH'S Table XXVIII. by simple inspection. The last column of this page contains the *Age* of the Moon, or the time elapsed since the preceding new moon, to tenths of days.

Pages V. to XII., inclusive, contain the *Moon's Right Ascension* and *Declination* for each day and hour of Greenwich *mean* time. They are accompanied with columns of *differences for one minute*, which also are given at each hour. The right ascension and declination of the moon change so rapidly, that, if they were not given at frequent intervals, the moon would cease to be useful to the practical navigator as a means of determining the latitude and time. These quantities are wanted for Greenwich mean time, which is either taken directly from a well-regulated chronometer, or is obtained by applying the longitude, turned into time, to the local time of the observer. Each is taken out for the day and hour of the Greenwich *mean* time; the *diff. for 1<sup>m</sup>* multiplied by the *minutes* and parts of a minute of the Greenwich time; and the product added to, or subtracted from, the quantity, according as the quantity is increasing or decreasing.

Thus, suppose the moon's right ascension and declination are required for 1869, Jan. 3, 15<sup>h</sup> 20<sup>m</sup> 16<sup>s</sup>, astronomical mean time at Greenwich:

	<i>Right Ascension.</i>			<i>Declination.</i>		
	<sup>h</sup>	<sup>m</sup>	<sup>s</sup>	<sup>°</sup>	<sup>'</sup>	<sup>"</sup>
Jan. 3, 15 <sup>h</sup>	12	2	0.64	3	34	48.4 N.
Diff. $2^{\circ}.2288 \times 20.267$	+ 45.17			— 11''.886 $\times 20.267$		
Jan. 3, 15 <sup>h</sup> 20 <sup>m</sup> 16 <sup>s</sup>	12	2	45.81	3	30	47.5 N.

The differences interpolated for  $10^m.133 = 0^h.17$  are for the right ascension  $2^{\circ}.2284$ , and for the declination  $-11''.888$ , which may be used for greater precision.

Page XII. contains also the *Phases of the Moon* and the dates of the *Moon's Perigee* and *Apogee*, or least and greatest distances from the earth.

Pages XIII. to XVIII., inclusive, contain the *Lunar Distances*, or the angular distances of the centre of the moon from the centre of the sun, the four larger planets, and certain fixed stars, as they would appear to an observer at the centre of the earth. They are given for every third hour of Greenwich mean time, beginning at noon; the dates are therefore *astronomical*. All the distances that can be observed on the same day are grouped together under that date; and the columns are read from left to right, across both pages of the same opening. The letter W., or E., is affixed to the name of the sun, planet, or star, to indicate that it is on the west, or east, side of the moon.

An observer on the earth's surface having measured a *Lunar Distance*, corrected it for errors of his instrument and for the semidiameter of the objects, and cleared it from the effects of refraction and parallax, finds the *true*, or *geocentric*, distance. With this distance and the distances in the Ephemeris of the same bodies on the same day, the *Greenwich mean time* of the observation can be found.

To lessen the labor of computation, there is given in the Ephemeris between every two successive distances the *logarithm of the seconds of time in which the distance changes 1''*,

or, as it is usually called, the *proportional logarithm of the difference*. It is given for the middle instant of the two dates between which it is placed.

For computing the Greenwich time we have the following rule:

Find in the Almanac the two distances between which the true distance falls; take out the nearest of these, the hours of Greenwich time over it, and the *P. L. of Diff.* between them:

Find the difference between the true distance and the distance taken from the Almanac; and from the *proportional logarithm* of this difference subtract the *P. L. of Diff.* taken from the Almanac:

The result is the *proportional logarithm* of an interval of time to be *added* to the hours of Greenwich time, taken from the Almanac, when the *earlier* Almanac distance is used: to be *subtracted* from the hours of Greenwich time, when the *later* Almanac distance is used.

Or, we may *add* the *common logarithm* of the difference of the true and the Almanac distances to the *P. L. of Diff.* of the Almanac; and the sum will be the *common logarithm* of the correction to be applied to the hours of Greenwich time. A Table of *Logarithms of small Arcs of Space and Time*, such as Table I. of the American Ephemeris before 1865, or Table IX. of CHAUVENET's *Lunar Method*, saves the operation of reducing degrees (or hours) and minutes to seconds, and the reverse.

As the *P. L. of Diff.* in the Ephemeris varies, the Greenwich time, found by the methods just described, may not be sufficiently exact. To correct it for such variation, or *2d difference*, take the difference between the *P. L. of Diff.* used and the one which follows it in the Ephemeris, (or, more strictly, half the difference of the preceding and following ones.) With this difference, and the first correction of the Greenwich time already found, enter Table I. App'x p. 10, and take out the corresponding seconds, which are to be *added* to the approximate Greenwich time if the *Prop. Logs.* in the Ephemeris are *decreasing*; to be *subtracted* if they are *increasing*.

Thus the *Greenwich mean time* of the observation can be obtained. If the observer has noted the time of observation by a chronometer, the difference of this chronometer time and the Greenwich mean time will be the *error* of the chronometer as found from the Lunar Distance. The agreement or disagreement of this error with that brought up from the error and rate of a previous date, may show whether the chronometer has run well or ill. In this way Lunar distances can be used as a check upon the chronometer. By a series of carefully observed Lunar Distances on both sides of the moon, the chronometer error can be tolerably well ascertained.

If the observer has found the *local mean time* of observation from the observed altitude of one of the bodies, or by a watch regulated to that time by recent observations, the difference of this local time and the Greenwich time found from the Lunar Distance will be his longitude.

As an example of finding the Greenwich mean time from a Lunar Distance, suppose that on 1869, Feb. 24, about 7<sup>h</sup> of Greenwich astronomical time, the corrected distance of the moon's centre from  $\alpha$  Tauri (*Aldebaran*) is  $64^{\circ} 13' 16''$ :

Corrected distance,	$64^{\circ} 13' 16''$			
Distance in the Ephemeris, Feb. 24, 6 <sup>h</sup> 0 <sup>m</sup> 0 <sup>s</sup>	$63^{\circ} 31' 31''$	P. L.	.2028	2028
Difference,	$41' 45''$	P. L.	.6346	6346
Time after 6 <sup>h</sup>	+ 1 6 36	P. L.	.4318	4318
Corr. for 2d Diff., Table I.,	+ 3	Diff. of P. Logs.	- 11	11
Greenwich Mean Time, Feb. 24,	7 6 39			

By a Table of common logarithms, or a Table of logarithms of small arcs, the reduction of the Greenwich time would be found thus :

P. L. from Ephemeris,		0.2028
Diff. of distances,	41' 45" = 2505"	log 3.3988
Red. of Greenwich time, + 1 <sup>h</sup> 6 <sup>m</sup> 36 <sup>s</sup> = 3996 <sup>s</sup>		log 3.6016

the result being the same as by the previous method.

Pages 218 to 241, inclusive, contain the Ephemeris of the four principal Planets, Venus, Mars, Jupiter, and Saturn. The Ephemeris of each consists of its *apparent right ascension and declination*, and their *variations in one hour*, for each Greenwich mean noon ; the *mean time of meridian passage* ; and, at the bottom of the page, the *semidiameter and horizontal parallax*.

North declinations are marked +, south declinations —. + prefixed to the hourly change of declination indicates that north declinations are increasing, and south declinations are decreasing ; — indicates that north declinations are decreasing, south declinations increasing.

The right ascension and declination are needed in all observations of the planet for time, latitude, or azimuth. The mode of reducing them to any instant of Greenwich mean time is the same as in the examples of the sun previously given. The mean time of passage across any meridian can be found by dividing the *daily* difference by 24, and using the *hourly* difference thus obtained, as in the case of the moon ; or, the reduction can be found by the proportion : As 24<sup>h</sup> (or 360°) is to the longitude, so is the daily difference to the reduction required.

Pages 242 to 244 contain the SUN's *Rectangular Coördinates* referred to the equator and equinox of the date. They were employed in computing the Ephemeris of the Planets. The day of the year, or number of days from January 0, is also given.

Pages 245 to 248 contain the MOON's *true longitude and latitude* for each Greenwich mean noon and midnight. The right ascensions and declinations of the moon have been computed from them.

Pages 261 to 264 contain the *Mean Places*, with their *annual variations*, of one hundred and ninety-eight Fixed Stars for the beginning of the year 1869. North declinations are marked + ; south declinations —.

The right ascension of a star is also the *sidereal time* of its meridian passage. From this we may roughly find the mean time of meridian passage by adding the *mean time of sidereal 0<sup>h</sup>* on page III. of the Calendar, or subtracting the *sidereal time of mean noon* on page II., (disregarding seconds ;) but we can find it more exactly by the processes already given for converting sidereal time to mean time.

The right ascension and declination of a star are generally needed in observations of it for time, latitude, or azimuth. The mean places are sufficiently accurate for most observations at sea ; but for more exact observations, the *apparent* places given on pages 265 to 325 should be used.

## THE ASTRONOMICAL PART.

This part is adapted to the meridian of Washington; and Washington time, *astronomical* or *sidereal*, is required in its use. The longitude of Washington from Greenwich is assumed to be  $+5^h 8^m 12^s$ .

*Obliquity of the Ecliptic, &c.*, page 250.—This page contains for every ten days of the year the *Apparent Obliquity*, which is required for the transformation of longitudes and latitudes to right ascensions and declinations, or the reverse; the *Equation of Equinoxes* in longitude and right ascension, or the reduction from the *mean* to the *true* equinox of the date; the *Precession of Equinoxes* in longitude, or the reduction of longitudes from the mean equinox of the *beginning* of the year to the mean equinox of the *date*; the *Sun's Aberration*, which is to be applied to the *true* longitude of the sun, as given in the Ephemeris, to obtain its *apparent* longitude; the *Sun's Horizontal Parallax*; and the *Mean Longitude of the Moon's Ascending Node*.

At the bottom of the page are given the *Mean Obliquity* for the beginning of the year; the *Annual Precession* for the middle of the year; the *logarithms* of the precession in a sidereal and in a solar day; and the *daily motion* of the moon's node in longitude.

*Fixed Stars.*—Pages 251–259 contain for each mean midnight the logarithms of *A*, *B*, *C*, *D*, also *f*, *G*, *H*, and logarithms of *g*, *h*, and *i*, (following BESSEL's notation), for reducing the *mean* places of the Fixed Stars at the beginning of the year to their *apparent* places on any day.

The formulæ from which they are derived, and those in which they are used, are given on page 260. The coefficients are those of PETERS and STRUVE. They are expressed in *arc*, but for right ascensions are readily converted to *time* by dividing by 15.

The first set of quantities require for the star the logarithms of *a*, *b*, *c*, *d*,\* *a'*, *b'*, *c'*, *d'*, which are to be found in the Star Catalogues. The other set require no other star constants than the right ascensions and declinations. *f*, *G*, and *H* are given in time, as well as *arc*, to facilitate their use with tables of sines, &c., which have the argument in time.

Tables IV., V., and VI., in the Appendix, give corrections of the apparent places of several circumpolar stars, and of the quantities *A* and *B* for small terms of nutation.

For a star near the pole, it is best to compute the reductions with the time constants and the mean right ascension and declination at the date, instead of the beginning of the year, (or the logarithms of *a*, *b*, *c*, &c., reduced to the date), and add such of the following terms as may be of sufficient magnitude:

In Right Ascension.		In Declination.	
$+0''.00004 \tau^2 \sin a$	$\left. \begin{array}{l} \tau^2 \sin a \\ \tau^2 \cos a \end{array} \right\} \tan \delta$	$+0''.000975 \tau^2 \sin^2 a$	$\left. \begin{array}{l} \tau^2 \sin^2 a \\ \cos 2 \Omega \\ \cos 2 \Omega \cos 2 a \\ \sin 2 \Omega \sin 2 a \\ \cos 2 \odot \\ \cos 2 \odot \cos 2 a \\ \sin 2 \odot \sin 2 a \end{array} \right\} \tan \delta$
$-0''.00224 \tau^2 \cos a$		$-0''.000023 \cos 2 \Omega$	
$-0''.000975 \tau^2 \sin 2 a$	$\left. \begin{array}{l} \tau^2 \sin 2 a \\ \sin 2 \Omega \cos 2 a \\ \cos 2 \Omega \sin 2 a \end{array} \right\} \tan^2 \delta$	$-0''.000080 \cos 2 \Omega \cos 2 a$	
$+0''.000154 \sin 2 \Omega \cos 2 a$		$-0''.000077 \sin 2 \Omega \sin 2 a$	
$-0''.000160 \cos 2 \Omega \sin 2 a$	$\left. \begin{array}{l} \sin 2 \odot \cos 2 a \\ \cos 2 \odot \sin 2 a \end{array} \right\} \sec^2 \delta$	$+0''.000040 \cos 2 \odot$	
$+0''.000930 \sin 2 \odot \cos 2 a$		$-0''.000467 \cos 2 \odot \cos 2 a$	$\left. \begin{array}{l} \sin 2 \odot \sin 2 a \\ \cos (\odot + \Omega) \\ \cos (\odot + \Omega) \cos 2 a \\ \sin (\odot + \Omega) \sin 2 a \\ \cos (\odot - \Omega) \\ \cos (\odot - \Omega) \cos 2 a \\ \sin (\odot - \Omega) \sin 2 a \end{array} \right\} \sin \delta \tan \delta$
$-0''.000933 \cos 2 \odot \sin 2 a$	$\left. \begin{array}{l} \sin (\odot + \Omega) \cos 2 a \\ \cos (\odot + \Omega) \sin 2 a \\ \sin (\odot - \Omega) \cos 2 a \\ \cos (\odot - \Omega) \sin 2 a \end{array} \right\} \tan \delta \sec \delta$	$-0''.000465 \sin 2 \odot \sin 2 a$	
$+0''.00077 \sin (\odot + \Omega) \cos 2 a$		$-0''.00004 \cos (\odot + \Omega)$	
$-0''.00076 \cos (\odot + \Omega) \sin 2 a$		$-0''.00038 \cos (\odot + \Omega) \cos 2 a$	
$+0''.00015 \sin (\odot - \Omega) \cos 2 a$		$-0''.00038 \sin (\odot + \Omega) \sin 2 a$	
$-0''.00008 \cos (\odot - \Omega) \sin 2 a$		$+0''.00038 \cos (\odot - \Omega)$	
		$-0''.00004 \cos (\odot - \Omega) \cos 2 a$	
		$-0''.00007 \sin (\odot - \Omega) \sin 2 a$	

Pages 261–264 contain the *mean places* and their *annual variations* of 198 Fixed Stars for 1869, Jan. 0<sup>h</sup>—407, or the instant when the sun's mean longitude was 280°.  $\tau$  on the preceding pages is reckoned from the same epoch. Stars within 25° of either pole are designated by a \*.

\*The logarithms of  $\frac{1}{15}$  of *a*, *b*, *c*, and *d* are given, so that the reductions of right ascensions shall be in time.

The *apparent* places of  $\alpha$ ,  $\delta$ , and  $\lambda$ , Ursæ Minoris, and of 51 Cephei, are given on pages 265–276 for every upper transit at Washington. They include the terms depending on  $2\text{C}$ , as well as other small terms on pages 260 and 504, so far as they were of sufficient importance.

The *apparent* places of the remaining 194 stars follow on pages 277–325 in the order of their right ascensions. They are given for every tenth transit, together with *ten times* their *daily* motion at transit; and include all terms of the preceding formulæ exceeding  $0^{\circ}.003$  in right ascension, or  $0^{\circ}.03$  in declination, except those which depend on  $2\text{C}$  and  $\text{C} - \text{I}'$ . The mean solar time of transit is also given to the nearest tenth of a day.

*Solar Ephemeris.*—Pages 326–331 contain the *Apparent Right Ascension* and *Declination* of the SUN for each mean and apparent noon at Washington; the *Hourly Motion* at mean noon; the *Equation of Time* at apparent noon with the sign of its application to apparent time; the SUN's *Semidiameter* and the *Sidereal Time of its passing the Meridian*; and the *Sidereal Time of Mean Noon*. The explanation of these quantities and their use has already been given on pages 497–499.

The SUN's *Horizontal Parallax* is on page 250.

*Moon Culminations.*—Pages 332–334 contain the mean solar time of the *Upper Transit* of the MOON's centre at Washington, expressed to hundredths of a minute; the *difference* for *one hour* of longitude, and the *Sidereal Time of Semidiameter passing the Meridian*, both given for the instant of transit at Washington. The numbers in the fifth column indicate the four STARS in the list of *Moon Culminating Stars*, pages 335–338, the two preceding and the two next following the moon, proper to be observed with the moon at each transit. The *bright Limb* of the Moon is indicated by the Roman numerals in the last column.

The time of transit at any place, within six hours of Washington in longitude, may be found with sufficient accuracy from the time of the Washington transit by using the hourly difference interpolated for a longitude *half* that of the given place. With this time, reduced to Greenwich time, the moon's right ascension can be taken from the Lunar Ephemeris, pages V–XII of each month, as in the example on page 501. If greater precision is required, or the place is more than six hours from Washington, we may from the right ascension thus obtained, which is nearly the *local sidereal time*, find the *local mean time* (as on page 500) more accurately than before, and thence the *Greenwich mean time*, and with this revise the computation.

As an example, suppose the right ascension of the bright limb of the moon to be required at the transit of April 25 at Rio Janeiro, Brazil, in longitude

E. from Washington,  $2^{\text{h}} 15^{\text{m}} 43^{\text{s}} = -2^{\text{h}}.262 = -0^{\text{d}}.0943$ .

W. from Greenwich,  $2^{\text{h}} 52^{\text{m}} 29^{\text{s}}$ .

Transit at Washington, (p. 332) . . . . .	April 25, 12	<sup>h</sup> 1.79
Hourly motion, . . . . .	$2^{\text{m}}.259 \times (-2.262) = -$	5.11
Transit at Rio Janeiro, . . . . .	April 25, 11	56.68
Longitude from Greenwich . . . . .	$+ 2$	52.48
Greenwich mean time . . . . .	April 25, 14	49.16
April 25, 14 <sup>h</sup> (p. 66), Moon's R. A. . . . .	14 11	20.03
Diff. for 1 <sup>m</sup> . . . . .	$2^{\text{s}}.3387 \times 49.16 = +$	1 54.97
April 25, 14 <sup>h</sup> 49 <sup>m</sup> .16, Moon's R. A. . . . .	14 13	15.00
Sid. time of semidiam. passing, (p. 332) . . . . .	$- 1$	9.01
R. A. of bright limb at its transit at Rio Janeiro . . . . .	14 12	5.99
The approximate Declination is $-8^{\circ} 9'$ .		

The above hourly motion,  $2^{\text{m}}.259$  is found by interpolating *back*  $0^{\text{d}}.047$  from that given on p. 332; and the change of right ascension in 1<sup>m</sup>,  $2^{\text{s}}.3387$ , by interpolating to 25<sup>m</sup> in *advance* of that given on p. 66 for April 25, 14<sup>h</sup>. The time of semidiameter passing the meridian is interpolated *back*  $0^{\text{d}}.094$

from that given on p. 332, and is *subtracted* from the right ascension of the centre, since the bright limb is I.,\* or the *preceding* one.

The Greenwich mean time computed from the right ascension of the moon's centre is 0<sup>m</sup>.012, and the revised right ascension 0<sup>m</sup>.03, less than those stated above.

*Moon Culminating Stars*, pages 335–338.—The *mean* places, with their annual variations, of 174 stars near the moon's path are given for the beginning of the fictitious year (1869, Jan. 0<sup>d</sup>—407). The names of 35 of them, whose *apparent* places are given in the Ephemeris of the *Fixed Stars*, are printed in SMALL CAPITALS.

The *apparent* places of the others may be obtained by the quantities and formulæ on pages 251–260. To illustrate the use of these, suppose the apparent place of No. 107, 2 Libræ, one of the four stars proper to be observed with the moon on the 25th April, to be required at its transit at Rio Janeiro at that date.

The Washington mean time of transit is April 25, 9<sup>h</sup>.7. The quantities from p. 251, or p. 255, are to be taken for a date 2<sup>h</sup>.3 = 0<sup>h</sup>.10 *before* midnight of April 25, for which they are there given.

## 1st Method.

The MOON'S *Semidiameter* and *Equatorial Horizontal Parallax* for each mean noon and midnight are on pages 339–342.† In the moon's ephemeris, as in that of the sun, the hourly motions belong to the instant for which they are given. The hourly motion of semidiameter is equal to .2723 times that of the horizontal parallax.

\* The moon is so nearly full, that limb II. is but slightly defective.

† For eclipses and occultations, BURCKHARDT'S value of the semidiameter, which is 2<sup>m</sup>.5 less, is preferred

The times of the *Moon's Phases, Apogee, Perigee, and greatest Libration*, are given on page 343; and the position of the *Moon's Equator* and the *Moon's mean longitude* on page 344.

The *Ephemerides of Mercury and Venus* (pp. 345–356) are given for *mean noon* and at *transit*, the mean time of which is in the last column; and those of the *exterior planets* (pp. 357–386) for *sidereal noon* and the time of transit. The column “day of the month” for the exterior planets contains the mean time of sidereal noon to the nearest tenth of a day.

The place of a planet for any number of minutes,  $t$ , from the *nearest noon* for which it is given,  $t$  being negative when the time precedes the noon, may be computed by the formulæ

$$\begin{aligned} a &= a_0 + t a' + t^2 b, \\ \delta &= \delta_0 + t \delta' + t^2 b', \end{aligned}$$

$a$  and  $\delta$  denoting the right ascension required,  $a_0$  and  $\delta_0$ , the right ascension and declination at the nearest *noon*;  $a'$  and  $\delta'$  their variations in one minute at noon. The logarithms of  $a$  and  $b$ ,  $a'$  and  $b'$ , are given with the ephemeris. For an interior planet,  $t$  must be expressed in minutes of *mean time*; for an exterior planet, in minutes of *sidereal time*. If  $t$  is restricted to  $12^h$ , the error of interpolation will not exceed  $\frac{1}{48}$  of the entire third difference.

The *Horizontal Parallaxes, Vertical Semidiameters and Sidereal Times of the Semidiameters passing the Meridian* are on pages 387 and 388.

The *Sun's Coördinates* (pp. 389–400) are given for each mean noon and midnight, referred to the apparent equinox and equator, and also to the mean equinox and equator at the beginning of the year (Jan. 0<sup>d</sup>.0). In the case of the rectangular coördinates, only the last four decimals are given for the mean equinox and equator, and the first three places are to be taken from the apparent equinox and equator. When a change of a unit is to be made in the third place, it is indicated by a corresponding colon (:). The latitude is referred to the ecliptic of the date. The reduction to the mean ecliptic of Jan. 0. is  $+0''.488 \tau \sin (\odot + 187^\circ)$ .

The *Heliocentric Coördinates* of the Planets (pp. 401–408) are referred to the mean equinox and ecliptic of the mean noon of the 2400,000th day of the Julian Period, and the dates for which they are given are counted from this epoch in mean solar days. They may be converted into days of the Julian Period by adding 2400,000. The columns  $-\frac{k^2}{r^3}x$ , &c., contain the quantities  $-1600 m \frac{k^2}{r^3}x$ ,  $-1600 m \frac{k^2}{r^3}y$ ,  $-1600 m \frac{k^2}{r^3}z$ , in units of the 7th decimal place, in which  $m$  denotes the mass of the planet, and  $k^2$  the unit of attractive force in the solar system, or  $\log k = 8.2355814$ .

Page 408 contains the *Inclinations and Longitudes of the Ascending Nodes* at the same epoch, and the logarithms of the *Masses*. The changes of the former in 100 days include the motions of the ecliptic and equinox.

*Eclipses*.—Pages 409–415 contain the elements necessary for computation and the principal phases of each eclipse of the SUN and MOON. The semidiameters of the moon are  $2''.5$ , and those of the sun  $2''.2$ , less than those in the Ephemeris.

The charts of the *Solar Eclipses* show the part of the world in which each is visible. The dotted curves pass through places, where the eclipse begins, or ends, at an exact hour of Washington mean time, and aid in finding an approximate time of the beginning, or ending, at any place. The limits and central line will give some idea of the magnitude of the eclipse. The longitudes are reckoned west from Washington.

The Tables of *Data of the Solar Eclipses* contain certain quantities\* derived from the elements and independent of the place of observation. They are given for successive

\* The formulæ are given in CHAUVENET'S *Spherical and Practical Astronomy*, Vol. I, page 513. The changes of  $A$ ,  $B$ , and  $C$  for one minute, or one second, are expressed in units of the sixth decimal place.

times at the Washington meridian; and if their values for the *Penumbra* be taken out for a time  $T_0$ , assumed near that of the beginning or end of the eclipse at any place, the prediction for that place may be computed quite accurately by the following formulæ:

Let  $\varphi$  = the latitude of the place, + when north,

$\lambda$  = its longitude from Washington, + when west,

$$\begin{aligned} (\text{Bessel.}) \quad \log e &= 8.912205, & \log(1 - e^2) &= 9.9970916, & \sin \chi &= e \sin \varphi, \\ h &= \sec \chi \cos \varphi, & k &= (1 - e^2) \sec \chi \sin \varphi. \\ a &= A - h \sin(\mu - \lambda), \\ b &= B - E k + G h \cos(\mu - \lambda), \\ c &= -C + F k - H h \cos(\mu - \lambda), \\ m &= \sqrt{b c} \quad (\text{usually with same sign as } a). \end{aligned}$$

If  $m = a$ , the time  $T_0$  is correctly chosen. If  $m$  differ from  $a$ , a correction  $t$  of the assumed time may be obtained in seconds by the formulæ,

$$\begin{aligned} \log \mu' &= 1.86167, & a' &= A' - \mu' h \cos(\mu - \lambda), \\ \tan \frac{1}{2} Q &= \frac{c}{m} = \frac{m}{b}, & b' &= B' - \mu' G h \sin(\mu - \lambda), \\ t &= \frac{1000000 (m - a)}{a' + b' \cot Q} \end{aligned}$$

and a new approximation to the actual Washington time will be

$$T_0' = T_0 + t,$$

with which the computation may be revised.

Thus successive approximations are made until for the last assumed time  $T_0$ ,  $m = a$  very closely, and  $t$  is quite small. The local mean time of the phenomenon will be, using the last values of  $T_0$  and  $t$ ,

$$T_0 + t - \lambda.$$

$Q$  must be taken of the same sign with  $a$ , and is a sufficiently near approximation to the angular distance of the point of contact reckoned from the *north* point of the sun's limb towards the *east*.

For a total or annular eclipse, the prediction of the interior contacts may be made in the same way, using the *Data* for the *Shadows*; except that  $Q$  will have a sign opposite that of  $a$  in a total eclipse.

To find  $V$ , the angular distance of the point of contact from the *Vertex* of the sun's limb towards the *east*, we have the formulæ

$$\begin{aligned} p \sin P &= \sin \varphi & c \sin C &= \cos P \tan(\mu - \lambda) \\ p \cos P &= \cos \varphi \cos(\mu - \lambda) & c \cos C &= \sin(P - \delta') \\ V &= Q - C, \end{aligned}$$

in which  $\delta'$  is the sun's declination.

If the values of  $Q$  at the beginning and at the end of the eclipse be found, and their difference (with regard to signs) be denoted by  $2\theta$ , the number of digits eclipsed is

$$12(1 + n) \sin^2 \frac{1}{2} \theta, \quad \text{or } 12(1 + n) \cos^2 \frac{1}{2} \theta,$$

according as  $\theta$  is acute or obtuse:  $n$  is the quotient of the semidiameter of the moon divided by that of the sun.

$\theta$  may also be found from the formulæ

$$\tan R = \frac{b'}{a'} \quad \theta = Q + R$$

(in which  $R$  has the sign of  $b'$ ); and the expression of  $t$  may be changed to

$$t = 1000000 \cdot \frac{m - a}{a'} \cdot \frac{\sin Q \cos R}{\sin \theta}.$$

The following is an example of the computation of the beginning of the Eclipse of August 7, 1869, for the Observatory at Washington, for which

$$\begin{aligned} \varphi &= +38^{\circ} 53' 39''.3 & \lambda &= 0^{\circ} 0' 0'' \\ (1) \quad \log e &= 8.912\ 205 \\ (2) \quad \text{l. sin } \varphi &= 9.797\ 8801 & (1) + (2) \quad \text{l. sin } \chi &= 8.710\ 085 \\ (3) \quad \log (1 - e^2) &= 9.997\ 0916 \\ (4) \quad \text{l. sec } \chi &= 0.000\ 5721 & (2) + (3) + (4) \quad \log k &= 9.795\ 5438 \\ (5) \quad \text{l. cos } \varphi &= 9.891\ 1505 & (4) + (5) \quad \log h &= 9.891\ 7226 \end{aligned}$$

By the chart, the Washington mean time of the beginning of the eclipse at Washington is  $5^{\text{h}} 2^{\text{m}}$ . Computation like the following gives as a second approximation to that time,  $T_0 = 5^{\text{h}} 2^{\text{m}}.45$ .

For a nearer approximation we take from the table for *Penumbra*, on page 415, the values of  $A$ ,  $B$ ,  $C$ , &c., for  $5^{\text{h}} 2^{\text{m}}.45$ .

*Computation of  $t$ , the correction of  $T_0$ .*

$$\begin{aligned} \mu &= 74^{\circ} 15' 16.1 & (9) \quad \log E &= 9.982898 \\ \mu - \lambda &= 74^{\circ} 15' 16.1 & (10) \quad \log k &= 9.795544 \\ & & (11) \quad \log F &= 9.981731 \\ (1) \quad \text{l. sin } (\mu - \lambda) &= 9.983390 & (9) + (10) \quad \log. E k &= 9.778442 \\ (2) \quad \log h &= 9.891723 & (10) + (11) \quad \log. $$\begin{aligned} \text{Assumed time, } & \dots \dots \dots T_0 = 5 \ 2 \ 27.00 \\ \text{Correction of the assumed time, } & \dots \dots \dots t = - 3.62 \\ \text{Washington mean time of beginning, } & \dots \dots \dots T_0 + t = 5 \ 2 \ 23.4 \end{aligned}$$

We shall also have  $C = 89^\circ 55'$  and the angle from the *Vertex*,  $V = -166^\circ 41'$ ;  $\phi = -95^\circ 14'$  and the magnitude of the eclipse 11.1 digits, or 0.93 of the sun's disc, on the south limb.

*Occultations.*—Pages 416–454 contain *Elements for facilitating the Prediction of Occultations of Planets and Stars by the Moon*. The list includes all stars to the  $6\frac{1}{2}$  magnitude in the *Catalogue of the British Association*, and a few others of less magnitude contained in the *Almanac Catalogue of Zodiacal Stars*, and chiefly belonging to clusters, which can be occulted during the year 1869.

The elements comprise the *Date, Name and Magnitude of the Star*; the *Limiting Latitudes* within which the occultation may be visible;

$\delta$  = Washington mean time of geocentric conjunction of the moon and stars in right ascension;

and at this time,

$H$  = Hour angle of the star at Washington, + when west,

$$X = \frac{15(\alpha - \alpha')}{\pi} \cos \delta = 0, \quad Y = \frac{\delta - \delta'}{\pi},$$

$$x' = \frac{15 \Delta \alpha}{\pi} \cos \delta, \quad y' = \frac{\Delta \delta}{\pi}, \text{ the hourly changes of } x \text{ and } y;$$

also  $\log \sin \delta'$  and  $\log \cos \delta'$ ;

in which  $\alpha$  and  $\delta$  are the true right ascension and declination of the moon,

$\Delta \alpha$  and  $\Delta \delta$ , their motions in one hour of mean time,

$\pi$ , the moon's equatorial horizontal parallax,

$\alpha'$  and  $\delta'$ , the apparent right ascension and declination of the star.

For any other Washington mean time  $T = \delta + t$ , we have ( $\mu$  being the sidereal equivalent of  $t$ , and  $t$  as a coefficient being expressed in hours)

$h = H + \mu$ , the star's hour angle at Washington,

$$x = t x', \quad y = Y + t y'.$$

The moon's motion is here regarded as uniform, the expressions for  $x$  and  $y$  are therefore more nearly correct the smaller the interval  $t$ . The exact values, to be employed in the reduction of an observed occultation, are

$$x = \frac{\sin(\alpha - \alpha') \cos \delta}{\sin \pi}$$

$$y = \frac{\sin(\delta - \delta') \cos^2 \frac{1}{2}(\alpha - \alpha') + \sin(\delta + \delta') \sin^2 \frac{1}{2}(\alpha - \alpha')}{\sin \pi}$$

in which  $\alpha$ ,  $\delta$  and  $\pi$  are to be taken from the Ephemeris for the time  $T$ . But for predicting the times of *immersion* and *emersion*, and the points on the moon's limb where these appearances take place, the preceding expressions suffice to enable the observer to determine when and where to watch for these phenomena.

For the place of observation, let

$\phi$  = its latitude, + when north;

$\lambda$  = its longitude from Washington, + when west;

$$(\text{Bessel.}) \log e = 8.9122 \ 05, \quad \log(1 - e^2) = 9.9970 \ 916,$$

$$\sin \chi = e \sin \phi, \quad E = (1 - e^2) \sec \chi, \quad F = \sec \chi.$$

The values of  $E$  and  $F$  and their logarithms are given for different latitudes in the following table :

$\varphi$	$E$ .	$F$ .	Log $E$ .	Log $F$ .
$0^\circ$	1—.0067	1.0000	9.9971	0.0000
$\pm 10$	1—.0066	1.0000	9.9971	0.0000
20	1—.0063	1.0004	9.9973	0.0002
30	1—.0059	1.0008	9.9975	0.0004
40	1—.0053	1.0014	9.9977	0.0006
50	1—.0047	1.0020	9.9979	0.0009
60	1—.0042	1.0025	9.9982	0.0011
70	1—.0037	1.0030	9.9984	0.0013
80	1—.0034	1.0033	9.9985	0.0014
90	1—.0033	1.0034	9.9985	0.0014

An occultation will not be visible unless,

1. The latitude of the place is included within the limiting parallels ;
2. At the time of occultation, or the local mean time ( $T-\lambda$ ), the sun is sufficiently below the horizon ;
3. At that time the star is above the horizon, or its local hour angle ( $h-\lambda$ ) is numerically less than  $\tau$  found by the formula

$$\cos \tau = -\tan \varphi \tan \delta'.$$

A table of  $\tau$ , or the hour angle of a body in the horizon, computed for different declinations, will be useful for such comparisons.

These conditions can generally be determined in advance, as in latitudes less than  $60^\circ$  ( $\delta-\lambda$ ) may be used instead of ( $T-\lambda$ ) except within two hours of sunrise or sunset ; and ( $H-\lambda$ ) instead of ( $h-\lambda$ ) except within half an hour of the star's rising or setting. For these exceptional cases, which, however, are not favorable for observation, the time of *apparent* conjunction in right ascension, or some nearer approximation to the time of occultation, can be subsequently employed.

The elements are given for the time of *geocentric* conjunction of right ascension of the moon and star. The time of *apparent* conjunction, as affected by parallax, may be found approximately by the following formulæ :

$$\begin{aligned} \mu' &= 54147.8 \sin 1'' = .2628 & u &= F \cos \varphi \sin (H-\lambda) \\ \log \mu' &= 9.41916 & u' &= \mu' F \cos \varphi \cos (H-\lambda) \end{aligned}$$

$$\text{In hours,} \quad (t) = \frac{u}{x' - u'}$$

$$\text{Washington time of apparent conjunction, } (T) = \delta + (t)$$

$$\text{Local " " " } (T) - \lambda$$

The value of ( $T$ ) to the nearest tenth of an hour is sufficiently accurate. If a closer approximation is desired, the computation may be repeated, using  $h=H+(\mu)$  instead of  $H$ ,

$$\begin{aligned} x &= (t) x' & (t') &= -\frac{x-u}{x'-u'} \\ (T') &= (T) + (t'). \end{aligned}$$

Let  $T = \delta + t$  be an assumed Washington mean time, it is convenient to take first the computed time of *apparent* conjunction, or some conjectural time near it. For this time find

$$h = H + \mu \quad x = t x' \quad y = Y + t y'.$$

A nearer approach to the time of either phase can be obtained by the following formulæ :

$$\begin{aligned}
 A \sin B &= E \sin \varphi & u &= F \cos \varphi \sin (h - \lambda) \\
 A \cos B &= F \cos \varphi \cos (h - \lambda)^* & v &= A \sin (B - \delta') \\
 & & u' &= \mu' A \cos B \\
 & & v' &= \mu' u \sin \delta'
 \end{aligned}$$

or, with other auxiliaries than  $A$  and  $B$ ,

$$\begin{aligned}
 b &= F \cos \varphi \cos (h - \lambda) & u' &= b \mu' \\
 v &= E \sin \varphi \cos \delta' - b \sin \delta'. \\
 m \sin M &= x - u & n \sin N &= x' - u' \\
 m \cos M &= y - v & n \cos N &= y' - v' \\
 (\text{Burckhardt.}) \quad k &= .27227 & \log k &= 9.43500 \\
 \cos \psi &= \frac{m \sin (M - N)}{k} & \psi &< 180^\circ
 \end{aligned}$$

	For Immersion.	For Emersion.
In hours,	$t_1 = -\frac{m \cos (M - N)}{n} - \frac{k \sin \psi}{n}$	$t_2 = -\frac{m \cos (M - N)}{n} + \frac{k \sin \psi}{n}$
Wash. mean time, $T_1 = T + t_1$		$T_2 = T + t_2$
Local " " $T_1 - \lambda$		$T_2 - \lambda$

Assuming now  $T_1 = \delta + t + t_1$  for the Immersion, or  $T_2 = \delta + t + t_2$  for the Emersion, as the Washington time instead of  $T$ , and recomputing, we can obtain\* nearer approximations to the times of these phenomena. But the first operation will give the times usually within one or two minutes, which is sufficiently accurate for watching for an immersion. For an emersion a more accurate knowledge is desirable; and for this purpose it will often be sufficient to substitute  $(h_2 - \lambda) = (h - \lambda + \frac{1}{2} \mu_2)$  for  $(h - \lambda)$  in the computation of  $u'$  and  $v'$ , and, using the same  $m$  and  $M$  as before, recompute  $n$ ,  $N$ ,  $\psi$  and  $t_2$ , a new correction to be added to  $T_2$ .

If  $\log. m \sin (M - N) = 9.4350$  nearly, a recalculation will generally be necessary to determine whether numerically,  $\cos \psi < 1$ , or  $\cos \psi > 1$ . In the latter case the impossible value of  $\cos \psi$  indicates that an occultation at the given place is impossible, except the computed distance from the moon's limb is within the errors of the Ephemeris of the moon and star.

In such cases of near approach to the moon's limb, we may take  $\psi = 0^\circ$ , or  $180^\circ$ , according as  $m \sin (M - N)$  is  $+$ , or  $-$ ; and for finding the time,

$$t = -\frac{m \cos (M - N)}{n}$$

The distance from the moon's limb is then

$$\pi (m \sin (M - N) - k),$$

disregarding the sign of  $m \sin (M - N)$ ; or, allowing for the augmentation of the semi-diameter,

$$\pi (m \sin (M - N) - k) (1 + z \sin \pi),$$

$$z = A \cos (B - \delta').$$

where

Having found satisfactorily the times of Immersion and Emersion, and therefore  $N$  and  $\psi$  in each case, we have as the angle from the *North point* of the moon's limb and reckoned towards the *West*,

$$\begin{aligned}
 Q &= 90^\circ - N - \psi & \text{for an immersion} \\
 Q &= 90^\circ - N + \psi & \text{for an emersion,}
 \end{aligned}$$

\* If  $(h - \lambda)$  be restricted to values numerically less than  $12^h$ , or  $180^\circ$ ,  $B$  may be taken in the same quadrant with  $(h - \lambda)$ , and have the same sign as the latitude. For a place where many occultations are observed, tables of  $A$ ,  $B$ ,  $u$  and  $u'$  for different values of  $(h - \lambda)$ , or of  $E \sin \varphi \cos \delta'$  for different declinations, would be convenient.

and, taking

$$c \sin C = u + t u'$$

$$c \cos C = v + t v',$$

in which the last value of  $t$  for the particular phase is properly used, we have as the angle from the *Vertex* of the moon's limb, or that point which is nearest the zenith,

$$V = Q + C$$

also reckoned towards the *West*.

For the image as seen through an inverting telescope, add to these angles  $180^\circ$ .

As a check on the accuracy of the work, we might recompute with the last determined time of immersion, or of emersion,  $u$ ,  $v$ ,  $x$ , and  $y$ , and we should have for either,

$$(x-u)^2 + (y-v)^2 = k^2 = 0.07413$$

$$\text{or,} \quad \log m = \log k = 9.4350$$

as the condition of the phenomenon:

Or, using the last computed values of the several quantities,

$$[(x-u) + t(x'-u')]^2 + [(y-v) + t(y'-v')]^2 = k^2 = 0.07413.$$

Greater values than these indicate that the computed time of immersion is too early, and of emersion too late, by a quantity proportional to the difference.

As an example, suppose it is required to find the times of immersion and emersion of  $\mu$  Ceti, February 17, 1869, at Chicago, Illinois, for which,

$$\phi = +41^\circ 53'$$

$$\lambda = 0^h 42^m 19^s.$$

The data for the computation are given on page 420. We see in advance that  $\phi$  is between the limiting latitudes; that  $(\phi - \lambda)$  is about  $7\frac{1}{4}^h$ , or two hours after sunset; and that  $(H - \lambda)$  is about  $2\frac{1}{4}^h$ , or four hours less than the star's hour angle at setting.

The constants for the place are:

1. $\sin \phi$	= 9.8245	1. $\cos \phi$	= 9.8719		
$\log E$	= 9.9977	$\log F$	= 0.0006	$\log \mu'$	= 9.4192
(1) $\log E \sin \phi$	= 9.8222	(2) $\log F \cos \phi$	= 9.8725	(3) $\log \mu' F \cos \phi$	= 9.2917

From page 420, for time of geocentric conjunction:

$\phi$	= $8^h 7^m.3$	$\phi - \lambda$	= $7^h 25^m.0$	$X$	= 0
$H$	= $+3^h 21^m 36^s$	$H - \lambda$	= $+2^h 39^m 17^s = +39^\circ 49'$	$Y$	= $+ .3714$
1. $\sin \phi'$	= 9.2202	$\phi' = +9^\circ 33'.5$		$x'$	= $+ .5314$
1. $\cos \phi'$	= 9.9939			$y'$	= $+ .1663$

First approximation to time of apparent conjunction:

(2) $\log F \cos \phi$	= 9.872	(3) $\log \mu' F \cos \phi$	= 9.292	$x'$	= $+ .531$
(4) 1. $\sin (H - \lambda)$	= 9.806	(5) 1. $\cos (H - \lambda)$	= 9.885	$u'$	= $+ .150$
(6) = (2) + (4) $\log u$	= 9.678	(7) = (3) + (5) $\log u'$	= 9.177	$x' - u'$	= $+ .381$
(8) $\log (x' - u')$	= 9.581			$\phi$	= $8^h 7^m.3$

$$\log (t) = 0.098$$

$$(t) = +1^h.25 = +1 \text{ } 15$$

Washington mean time,

$$(T) = \phi + (t) = 9 \text{ } 22.3$$

For this time:

(9) $\mu' = +1 \text{ } 15 \text{ } 12^s$	(25)	$X$	= 0
(10) $H - \lambda = +2 \text{ } 39 \text{ } 17$	(26)	$1.25 \times .5314 = (t) x'$	= $+ .6642$
(11) = (9) + (10) $\lambda - \lambda = +3 \text{ } 54 \text{ } 29 = 58^\circ 37'$	(27)	$Y$	= $+ .3714$
(12) 1. $\sin (\lambda - \lambda) = 9.9313$	(28)	$1.25 \times .1663 = (t) y'$	= $+ .2079$

		(59)=(53)+(56)+(57)	$\log \frac{k}{n} \sin \psi = 9.7688$

\* A large portion of this computation may be made by the Traverse Table instead of logarithms.

$$\begin{aligned}
 -\frac{m}{\pi} \cos (M-N) &= -\frac{h}{0.050} \\
 +\frac{k}{\pi} \sin \psi &= +0.587 \\
 t_2 &= +0.537 = +0^{\text{h}} 32.2^{\text{m}} \\
 (T) &= 9^{\text{h}} 22.3^{\text{m}} \\
 \text{Washington mean time} \quad T_2 &= 9^{\text{h}} 54.5^{\text{m}} \\
 \text{Chicago} \quad \text{"} \quad \text{"} \quad T_2 - \lambda &= 9^{\text{h}} 12.2^{\text{m}}
 \end{aligned}$$

Pages 455–457 contain a list of such occultations and near approaches as will be visible at Washington during the year 1869. For the latter, the time of nearest approach, the nearest point of the moon's limb, and the distance of the star from the moon's limb, are stated.

At the end of the Appendix will be found a list of most of the occultations, which will be visible between  $30^\circ$  and  $45^\circ$  north latitude, and  $1^{\text{h}} 30^{\text{m}}$  and  $3^{\text{h}}$  longitude west from Washington during the years 1868 and 1869. The times of immersion and emersion in Washington mean time, and the angle from the vertex at emersion, are given for each  $5^\circ$  of latitude and each  $30^{\text{m}}$  of longitude between the above limits, and can easily be found by interpolation for intermediate points.

*Jupiter's Satellites*, pages 458–490.—These pages contain for the several Satellites—

1. The Washington mean times of the occultations, eclipses, transits and transits of shadows, arranged in the order of time. W, after a phase, indicates such as are visible at Washington, or which occur when the sun is more than  $8^\circ$  below and Jupiter more than  $8^\circ$  above the horizon of that place.

2. A diagram for each month constructed for the eclipse which occurs nearest the middle of the month, showing the phases of the eclipse for an inverting telescope. The stars indicate the points of disappearance and reappearance, distinguished by  $d$  and  $r$ . The space between them shows the position of the shadow of the planet.

3. Washington mean time of geocentric superior conjunction, arranged for each planet separately.

4. The rectangular coördinates  $x'$  and  $y'$  for successive times reckoned from the next preceding superior conjunction, computed for a constant major axis and maximum minor axis of the apparent ellipse described by the satellite as seen from the sun at its mean distance from the planet.

5. The *factors* by which  $x'$  and  $y'$  are to be multiplied to obtain the actual coördinates  $x$  and  $y$  for the apparent ellipse, as seen from the earth at any date; the inclination  $p$  of the minor axis to the circle of declination, reckoned from the *north*, positive towards the *east*; and the actual coördinates  $x$  and  $y$  at the times of eclipse of each satellite.

The coördinates are referred to the centre of the primary and the major and minor axis of the ellipse described by the satellite, and are expressed in seconds of arc.  $x$  is positive when on the *east* side of the planet;  $y$  is positive when *north*. By means of them the configurations of the satellite can be found at any time.

The *Elements of Saturn's Ring*, page 491, give the *apparent* magnitude and position of its several components for each 20 days. The *apparent Discs* of Venus and Mars are given on the same page for the 15th of each month.

The *Phenomena*, pages 492, 493, include the times of conjunction, opposition and quadrature, perihelion and aphelion, stationary points, and conjunction in right ascension with the moon, of the principal planets.

The *Positions of the Principal Observatories* are given on pages 494, 495.

In the Appendix will be found tables of corrections of the Ephemerides of Venus and Mars on pages 218-229, to adapt them to the adopted elements; a table of reductions of the mean places of the Standard Stars to those adopted in the American Ephemeris for 1870; and an Ephemeris of Neptune for the years 1866 to 1869, computed from the Tables of Professor Newcomb.

# APPENDIX.

## CONSTRUCTION OF THE ASTRONOMICAL AND NAUTICAL EPHEMERIDES FOR 1869.

---

THE Precession of the Equinoxes, the Mean Obliquity of the Ecliptic, and the Constant of Aberration (p. 250) are taken from STRUVE and PETERS. They are :

$$\begin{aligned}\text{Precession}^* &= 50''.2411 + 0''.0002268 t, \\ \text{Obliquity}^\dagger &= 23^\circ 27' 54''.22 - 0''.4645 t - 0''.0000014 t^2, \\ \text{Aberration}^\ddagger &= 20''.4451 \pm 0''.0111,\end{aligned}$$

in which  $t$  is the number of years after 1800.

The Nutation of the Apparent Obliquity and the Equation of the Equinoxes are computed from PETERS' formulæ given in his *Numerus Constans Nutationis*, pp. 46-48, and reprinted in the volume of this Ephemeris for 1855. These quantities have been used in all computations relating to the Fixed Stars.

The General Constants for Star Reduction are computed from tables adapted to the formulæ given on page 260.

In the Ephemerides of the Sun, Moon, and Planets, the Obliquity of the Ecliptic and the Nutation of HANSEN and OLUFSEN's *Tables du Soleil* have been used. The Aberration in these tables,  $20''.255$ , has been used in the Ephemeris of the Sun. The Mean Obliquity exceeds that of PETERS by  $0''.37$ .

The Mean Places of 48 Northern Circumpolar Stars, and the Mean Right Ascensions of 128 Time Stars, have been taken from the *Standard Mean Right Ascensions of Circumpolar and Time Stars, prepared for the use of the U. S. Coast Survey* by Dr. B. A. GOULD, Washington, 1862.

The Mean Places of 4 Southern Circumpolar Stars are derived from the *British Nautical Almanac* for 1848. The authorities for the Mean Declinations of the 128 Time Stars and the Mean Places of the remaining 18 Stars are stated in the Appendix to the *American Ephemeris and Nautical Almanac* for 1865.

In the nomenclature of the Fixed Stars, (H) signifies that HEVELIUS's number, (B) that BODE's notation has been used. Duplicate notations have been added in a few cases. The magnitudes, except of stars south of  $-40^\circ$  dec., are ARGELANDER's.

The reductions from the Mean to the Apparent Places of the Stars contained in WOLFER's *Tabulæ Reductionum* have been derived from that work; except that generally the proper motions derived from the authorities referred to in the Ephemeris for 1865 have been employed, and for Polaris  $-0''.07 \tau^2$  has been applied, and the term depending on  $\zeta - \iota'$  omitted.

The reductions of the remaining 154 stars have been taken from tables similar to those of WOLFER's. They include the terms of the formulæ on pages 260 and 504, so far as sensible, except those depending on the moon's longitude. The terms depending on  $2 \zeta$  have, however, been applied to the four stars whose places are given for every day. The values of these terms for seven circumpolar stars, computed for 1870.0, are given in the Table IV. of this Appendix.

---

\* PETERS' *Numerus Constans Nutationis*, p. 71.  
† STRUVE's *Constant de l'Aberration*, p. 47.

† Ibid., pp. 66 and 71.

## APPENDIX.

The right ascension of Sirius includes the term given by PETERS,\*

$$q = 0^{\circ}.127 + 0^{\circ}.00050 (t - 1800) + 0^{\circ}.171 \sin (u + 77^{\circ} 44')$$

in which  $u$ , the eccentric anomaly from the inferior apsis, is found by the formula

$$u - e \sin u = n (t - T),$$

from the elements

$T = 1791.431$ , passage through the inferior apsis,

$e = 0.7994$ , the eccentricity,

$n = 7^{\circ}.1865$ , mean annual motion in orbit,

$50^{\circ}.093$ , period of revolution.

The Mean Places of such of the Moon-culminating Stars as are not found in the list of standard stars, have been taken in order of preference from the *Almanac Catalogue of Zodiacal Stars printed for the use of the American Ephemeris and Nautical Almanac*, Washington, 1864; the *Greenwich Twelve-Year Catalogue*; and the *Catalogue of the British Association*.

The Ephemeris of the Sun is constructed from HANSEN and OLUFSEN's *Tables du Soleil*, Copenhagen, 1853. The Sun's rectangular equatorial coördinates have been computed from the longitudes and latitudes by the following formulæ:

$$X = R \cos \lambda$$

$$Y = R \sin \lambda \cos \omega - 19.3 R \delta$$

$$Z = R \sin \lambda \sin \omega + 44.5 R \delta$$

$$X' = X + Y \sec \omega \Delta \lambda$$

$$Y' = Y - X \cos \omega \Delta \lambda + Z \Delta \omega - 9.4 \tau R \sin (\odot + 187^{\circ})$$

$$Z' = Z - X \sin \omega \Delta \lambda - Y \Delta \omega + 21.7 \tau R \sin (\odot + 187^{\circ})$$

in which  $\lambda$ ,  $\delta$  and  $\omega$  are referred to the equinox and ecliptic of the date;  $\Delta \lambda$  is the reduction of longitude for precession and nutation from Jan. 0;  $\Delta \omega$  the reduction of the mean to the apparent obliquity;  $\tau$  the part of the year since Jan. 0; and the numerical coefficients are in units of the 7th place.

The Sun's Horizontal Parallax at the Earth's mean distance has been taken from ENCKE's discussion of the Transits of Venus in 1761 and 1769, equal to  $8''.5776$ . Later discussions give a value  $0''.3$  greater. The Sun's Semidiameter at the Earth's mean distance has been taken as  $16' 2''$ .

The Ephemeris of the Moon has been constructed from PEIRCE's *Tables of the Moon*, 2d edition, Washington, 1865. They include the *Tables of the Moon's Parallax* constructed from WALKER's and ADAMS's formulæ.

The Semidiameter of the Moon has been computed from the Moon's Horizontal Parallax by the formula,

$$S = .272274 \pi + 2''.5.$$

A semidiameter  $2''.5$  less is found to be better adapted for the computation of eclipses and occultations.

The Ephemeris of Mercury has been derived from the Tables of Prof. WINLOCK, which are based on the theory of LE VERRIER, published in the *Additions to the Connaissance des Temps* for 1848.

The Ephemeris of Venus has been derived from manuscript Tables, constructed from LINDENAU's Tables, in a form similar to that adopted for the Lunar Tables: applying AIRY's Long Equation and the corrections proceeding from the discussion, by the method

---

\* *Astronomische Nachrichten*, Nr. 748, "Elemente V."

## CONSTRUCTION OF THE ALMANAC.

of Least Squares, of Mr. HUGH BREEN's results contained in his paper on the *Corrections of LINDENAU's Elements of the Orbit of Venus, &c.*, published in the *Memoirs of the Royal Astronomical Society*, Vol. XVIII.; and adopting the secular variations of the elements from LE VERRIER's *Memoir on the Determination of the Secular Inequalities of the Planets*, which appeared in the *Connaissance des Temps* for the year 1844. The following are the corresponding corrected elements, and annual variations for Washington, 1855.0:

$$\begin{aligned} L &= 289^{\circ} 51' 53.5 + 2106691''.706 t. \\ \pi &= 129 32 59.6 + 49''.57459 t. \\ Q &= 75 23 27.3 + 32''.88424 t. \\ i &= 3 23 34.6 + 0''.04363 t. \\ e &= 1410''.6847 - 0''.11157 t. \\ n &= 2106641''.438 \\ a &= 0.7233323 \end{aligned}$$

The Ephemeris of Mars is derived from manuscript Tables constructed from LINDENAU's Tables in the same manner as the Tables of Venus. Mr. HUGH BREEN's results contained in his paper *On the Corrections of LINDENAU's Elements of Mars*, published in the *Memoirs of the Royal Astronomical Society*, Vol. XX., have also been discussed and applied; and LE VERRIER's secular variations of the elements are likewise adopted. The following are the corresponding corrected elements, and secular variations for Washington, 1855.0:

$$\begin{aligned} L &= 320^{\circ} 13' 33.87 + 689101''.1527 t. \\ \pi &= 333 23 17.84 + 65''.9990 t. \\ Q &= 48 25 55.29 + 27''.6997 t. \\ i &= 1 51 2.20 - 0''.02141 t. \\ e &= 19238''.75 + 0''.18549 t. \\ n &= 689050''.8927 \\ a &= 1.5236915 \end{aligned}$$

The Ephemeris of Jupiter is derived from manuscript Tables constructed from BOUVARD's Tables, with such changes as were required to make them correspond more nearly to the formulæ.

The Ephemeris of Saturn is derived from BOUVARD's Tables. The perturbations produced by Jupiter, and the change of the Great Inequality since 1840, have been increased by  $\frac{1}{36}$  of their value. ADAMS's Table in the *British Nautical Almanac* for 1851 has been substituted for BOUVARD's Table XLII. The following corrections of the elements for 1855.0 have also been introduced:

corr. mean long.	= + 4''.9
corr. long. of node	= - 143''.0
corr. inclination	= - 5''.7 + 0''.0149 t.

The Ephemeris of Uranus is derived from the elliptical portion of BOUVARD's Tables, with LE VERRIER's corrections and perturbations caused by Jupiter and Saturn, contained in his *Recherches sur les Mouvements de la Planète Herschel (dite Uranus)*, published in the *Connaissance des Temps* for 1849, and also PEIRCE's corrections and perturbations arising from the influence of Neptune.

The Ephemeris of Neptune is derived from PEIRCE's theory and WALKER's orbit.

An Ephemeris for 1866-9, derived from Prof. NEWCOMB's *Tables of Neptune*, Washington, 1866, is given on pages 21-27 of this Appendix.

## APPENDIX.

The eclipses and elongations of Jupiter's Satellites are computed from DAMOISEAU's Tables. The semidiameters of the Planets are computed from the following values :

	Semidiameter.	Log Dist.	Authority.
Mercury	3.34	0.00	LE VERRIER, <i>Theory of Mercury</i> .
Venus	$8.546 \pm 0.086$	0.00	
Mars (polar)	$2.842 \pm 0.057$	0.25	PEIRCE, from the Washington Observations of 1845 and 1846, made with the mural circle.
Jupiter (polar)*	$18.78 \pm 0.067$	0.70	
Saturn (polar)	$8.77 \pm 0.039$	0.95	
Uranus	$1.68 \pm 0.3$	1.30	
Jupiter (equat.)	20.00	0.70	
Saturn (equat.)	9.38	0.95	

To correspond to the apparent semidiameters observed with the Washington mural circle, all the semidiameters, except those of Mercury, computed from these values, must be increased by the constant quantity,  $0''.57$ .

The apparent elements of Saturn's Rings are computed from BESSEL's data, except those for Bond's dusky ring.

The Tables for the eclipses of the sun are adapted to the modification of BESSEL's formulæ, suggested by T. HENRY SAFFORD, jr. The formulæ are given in PEIRCE's *Spherical Astronomy* and CHAUVENET's *Spherical and Practical Astronomy*, Vol. I.

The elements for occultations of stars by the moon are adapted to BESSEL's method in the *Astronomische Nachrichten*, Vol. VII., and the *Berliner Astronomisches Jahrbuch* for 1831. The formulæ are also to be found in CHAUVENET's *Astronomy*.

The Heliocentric Coördinates of the Planets are given for the computation of perturbations, and the following are the values of the masses, that of the Sun being unity :

Mercury	$\frac{1}{4865751}$	ENCKE, <i>A. N.</i> , No. 443.
Venus	$\frac{1}{390000}$	LE VERRIER, <i>Théor. de Merc.</i> , p. 115.
The Earth	$\frac{1}{354936}$	LE VERRIER, <i>Théor. de Merc.</i> , p. 26.
Mars	$\frac{1}{2680637}$	BURCKHARDT, <i>Conn. des Temps</i> , 1816, p. 343.
Jupiter	$\frac{1}{1047.879 \pm 0.235}$	BESSEL, <i>Die Masse des Jupiter</i> , p. 64
Saturn	$\frac{1}{3501.6}$	BESSEL, <i>Comptes Rendus</i> , 1841.
Uranus	$\frac{1}{24905}$	LAMONT, <i>Mem. Ast. Soc.</i> , Vol. XI., p. 54.
Neptune	$\frac{1}{15780}$	PEIRCE, <i>Am. Ac. Proc.</i> , Vol. I., p. 333.

The intervals of original computation have in all cases been made sufficiently small to authorize the use of the differences as a check of the accuracy of the work. The results have also been tested, in various portions, by means of duplicate computations. The proofs from the electrotypes plates have been thoroughly examined by an independent series of differences. And it is believed that, in every respect, that system has been adopted in which accuracy was most likely to be secured.

---

\* In the volumes for 1858 to 1869 inclusive 19''.19, from the Appendix for 1855, has been used for the Washington Ephemeris.

# CONSTRUCTION OF THE ALMANAC.

The principal computations of the Ephemeris have been distributed in the following manner :

The Sun has been computed by Mr. EASTWOOD; the Ephemeris of the Moon and the Lunar Distances by Professor RUNKLE, Mr. WRIGHT, and Mr. FERREL. Mercury has been computed by Mr. AUSTIN, Venus by Miss MITCHELL, Mars by Mr. EASTWOOD and Mr. OLIVER, Jupiter by Professor KENDALL, Saturn by Professor VAN VLECK, Uranus by Mr. FERREL, and Neptune by Professor KENDALL. The Fixed Stars and the General Constants for Reduction have been computed by Mr. G. W. HILL, and the Occultations by Mr. DOWNES and Mr. WIESSNER. The Eclipses have been computed and the Charts projected by Mr. WRIGHT. The Ephemeris of Neptune from NEWCOMB's Tables has been prepared by Mr. WIESSNER; and the Occultations visible West of the Mississippi by Mr. H. B. HILL.

45	0.6	55	1 2.8	135					

$\Delta \lambda$  has the sign of  $\tan. (\lambda - \Omega)$

$a$  has the sign of  $\cos. (\Omega - \lambda)$

$B$  has the sign of  $\sin. (\Omega - \lambda)$

When  $\Omega - \lambda$  exceeds  $180^\circ$  the table is to be entered with  $(\Omega - \lambda) - 180^\circ$  as the argument in the column  $\Omega - \lambda$ .
